

# Leprosy-like cutaneous presentation in histoplasmosis

## Manifestazione cutanea simil-leprosa in corso di istoplasmosi

**D**ear Editor, the recent report on the case of an HIV+ patient with leprosy-like cutaneous presentation of histoplasmosis is very interesting [1]. Indeed, the rare clinical manifestation of histoplasmosis, which is usually difficult to diagnose, can be seen. However, the skin manifestation is not extremely rare and disseminated cutaneous histoplasmosis is a condition to be kept in mind in the management of HIV+ patients [2]. Nevertheless, the co-presentation of leprosy and HIV infection is not impossible. In such cases, the atypical skin manifestation can be seen and final diagnosis may be made more difficult [3].
